7.4.26 Contractible spaces

The definition (which agrees with "contractible" on subsets of Euclidean space) is a little cryptic because we don't in fact assume that the constant "a" is in the space. This forces the convention that the empty space / set is contractible, avoiding some special cases.

definition *contractible_space* **where**

7.4.30 Nullhomotopic mappings

A mapping out of a sphere is nullhomotopic iff it extends to the ball. This even works out in the degenerate cases when the radius is ≤ 0, and we also don't need to explicitly assume continuity since it's already implicit in both sides of the equivalence.

```
lemma nullhomotopic_from_lemma:
  assumes contg: continuous_on (cball a r − {a}) g
      and fa: ⋀e. 0 < e
              ⟹ ∃ d. 0 < d ∧ (∀ x. x ≠ a ∧ norm(x − a) < d ⟶ norm(g x − f

7.8 Infinite sums

In this theory, we introduce the definition of infinite sums, i.e., sums ranging over an infinite, potentially uncountable index set with no particular ordering. (This is different from series. Those are sums indexed by natural numbers, and the order of the index set matters.)

Our definition is quite standard: $s := \sum_{x\in A} f(x)$ is the limit of finite sums $s_F := \sum_{x\in F} f(x)$ for increasing F. That is, s is the limit of the net s_F where F are finite subsets of A ordered by inclusion. We believe that this is the standard definition for such sums. See, e.g., Definition 4.11 in [2]. This definition is quite general: it is well-defined whenever f takes values in some commutative monoid endowed with a Hausdorff topology. (Examples are reals, complex numbers, normed vector spaces, and more.)

The converse of *abs_summable_summable* does not hold: Consider the Hilbert space of square-summable sequences. Let e_i denote the sequence with 1 in the ith position and 0 elsewhere. Let $f(i) := e_i/i$ for $i \geq 1$. We have $\neg$ *f abs_summable_on UNIV* because $\|f(i)\| = 1/i$ and thus the sum over $\|f(i)\|$ diverges. On the other hand, we have *f summable_on UNIV*; the limit is the sequence with $1/i$ in the ith position.

(We have not formalized this separating example here because to the best of our knowledge, this Hilbert space has not been formalized in Isabelle/HOL yet.)

The following lemma indeed needs a complete space (as formalized by the premise *complete UNIV*). The following two counterexamples show this:

- Consider the real vector space V of sequences with finite support, and with the ℓ_2-norm (sum of squares). Let e_i denote the sequence with a 1 at position i. Let $f : \mathbb{Z} \to V$ be defined as $f(n) := e_{|n|}/n$ (with $f(0) := 0$). We have that $\sum_{n\in\mathbb{Z}} f(n) = 0$ (it even converges absolutely). But $\sum_{n\in\mathbb{N}} f(n)$ does not exist (it would converge against a sequence with infinite support).
- Let f be a positive rational valued function such that $\sum_{x\in B} f(x)$ is $\sqrt{2}$ and $\sum_{x\in A} f(x)$ is 1 (over the reals, with $A \subseteq B$). Then $\sum_{x\in B} f(x)$ does not exist over the rationals. But $\sum_{x\in A} f(x)$ exists.

The lemma also requires uniform continuity of the addition. And example of a topological group with continuous but not uniformly continuous addition would be the positive reals with the usual multiplication as the addition. We do not know whether the lemma would also hold for such topological groups.

The lemmas *infsum_comm_additive_general* and *infsum_comm_additive* (and variants) below both state that the infinite sum commutes with a continuous additive function. *infsum_comm_additive_general* is stated more for more general type classes at the expense of a somewhat less compact formulation of the premises. E.g., by avoiding the constant *additive* which introduces an additional sort constraint (group instead of monoid). For example, extended reals (*ereal*, *ennreal*) are not covered by *infsum_comm_additive*.

7.8.7 Infinite sums of formal power series

Consequently, a family $(f_x)_{x\in A}$ of formal power series sums to a series s iff for any $n \geq 0$, the set $A_n = \{x \in A \mid [X^n]\, f_x \neq 0\}$ is finite and $[X^n]\, s = \sum_{x\in A_n} [X^n]\, f_x$.

The first condition can be rephrased as follows: for any $n \geq 0$, for all but finitely many x, the series f_x has subdegree $> n$.

lemma *has_sum_fpsI*:
assumes $\bigwedge n$. *finite* $\{x{\in}A.\ fps\_nth\ (F\ x)\ n \neq 0\}$

7.11.20 Theorems from Kuratowski

Kuratowski, Remark on an Invariance Theorem, *Fundamenta Mathematicae* **37** (1950), pp. 251-252. The idea is that in suitable spaces, to show "number of components of the complement" (without distinguishing orders of infinity) is a homeomorphic invariant, it suffices to show it for closed subsets. Kuratowski states the main result for a "locally connected continuum", and seems clearly to be implicitly assuming that means metrizable. We call out the general topological hypotheses more explicitly, which do not however include connectedness.

Continuity of addition

The next few lemmas remove an unnecessary assumption in *tendsto_add_ereal*, culminating in *tendsto_add_ereal_general* which essentially says that the addition is continuous on ereal times ereal, except at $(-\infty, \infty)$ and $(\infty, -\infty)$. It is much more convenient in many situations, see for instance the proof of *tendsto_sum_ereal* below.

lemma *tendsto_add_ereal_PInf*:
fixes $y :: ereal$
assumes *y*: $y \neq -\infty$
assumes *f*: $(f \longrightarrow \infty)\ F$ **and** *g*: $(g \longrightarrow y)\ F$

7.15.8 Tannery's Theorem

Tannery's Theorem proves that, under certain boundedness conditions:

$$\lim_{x\to\bar{x}} \sum_{k=0}^{\infty} f(k,n) = \sum_{k=0}^{\infty} \lim_{x\to\bar{x}} f(k,n)$$

7.16.7 The strong operator topology on continuous linear operators

Let $'a$ and $'b$ be two normed real vector spaces. Then the space of linear continuous operators from $'a$ to $'b$ has a canonical norm, and therefore a canonical corresponding topology (the type classes instantiation are given in `Bounded_Linear_Function.thy`).

However, there is another topology on this space, the strong operator topology, where T_n tends to T iff, for all x in $'a$, then $T_n\ x$ tends to $T\ x$. This is precisely the product topology where the target space is endowed with the norm topology. It is especially useful when $'b$ is the set of real numbers, since then this topology is compact.

We can not implement it using type classes as there is already a topology, but at least we can define it as a topology.

Note that there is yet another (common and useful) topology on operator spaces, the weak operator topology, defined analogously using the product topology, but where the target space is given the weak-* topology, i.e., the pullback of the weak topology on the bidual of the space under the canonical embedding of a space into its bidual. We do not define it there, although it could also be defined analogously.

blast+
qed

Invertible derivative continuous at a point implies local injectivity. It's only for this we need continuity of the derivative, except of course if we want the fact that the inverse derivative is also continuous. So if we know for some other reason that the inverse function exists, it's OK.

7.17.23 The concept of continuously differentiable

John Harrison writes as follows:

"The usual assumption in complex analysis texts is that a path γ should be piecewise continuously differentiable, which ensures that the path integral exists at least for any continuous f, since all piecewise continuous functions are integrable. However, our notion of validity is weaker, just piecewise differentiability... [namely] continuity plus differentiability except on a finite set... [Our] underlying theory of integration is the Kurzweil-Henstock theory. In contrast to the Riemann or Lebesgue theory (but in common with a simple notion based on antiderivatives), this can integrate all derivatives."

"Formalizing basic complex analysis." From Insight to Proof: Festschrift in Honour of Andrzej Trybulec. Studies in Logic, Grammar and Rhetoric 10.23 (2007): 151-165.

And indeed he does not assume that his derivatives are continuous, but

the penalty is unreasonably difficult proofs concerning winding numbers. We need a self-contained and straightforward theorem asserting that all derivatives can be integrated before we can adopt Harrison's choice.

This function returns the angle of a complex number from its representation in polar coordinates. Due to periodicity, its range is arbitrary. *Arg2pi* follows HOL Light in adopting the interval $[0,2\pi)$. But we have the same periodicity issue with logarithms, and it is usual to adopt the same interval for the complex logarithm and argument functions. Further on down, we shall define both functions for the interval $(-\pi,\pi]$. The present version is provided for compatibility.

7.20.33 Normalisation of angles

The following operation normalises an angle φ, i.e. returns the unique ψ in the range $(-\pi, \pi]$ such that $\varphi \equiv \psi \pmod{2\pi}$. This is the same convention used by the *Arg* function.

definition *normalize_angle* :: *real* ⇒ *real* **where**
*normalize_angle x = x − ⌈x / (2 * pi) − 1 / 2⌉ * (2 * pi)*

lemma *normalize_angle_id* [*simp*]:

7.20.34 Convexity of circular sectors in the complex plane

In this section we will show that if we have two non-zero points w and z in the complex plane whose arguments differ by less than π, then the argument of any point on the line connecting w and z lies between the arguments of w and z. Moreover, the norm of any such point is no greater than the norms of w and z.

Geometrically, this means that if we have a sector around the origin with a central angle less than π (minus the origin itself) then that region is convex.

lemma *Arg_closed_segment_aux1*:

8.1 Sigma Algebra

Sigma algebras are an elementary concept in measure theory. To measure — that is to integrate — functions, we first have to measure sets. Unfortunately, when dealing with a large universe, it is often not possible to consistently assign a measure to every subset. Therefore it is necessary to define the set of measurable subsets of the universe. A sigma algebra is such a set that has three very natural and desirable properties.

8.1.1 Families of sets

locale *subset_class* =
fixes Ω :: *'a set* **and** M :: *'a set set*
