Chapter 1

Preface

1.1 Introduction

This document contains the automatically generated listings of the Isabelle sources for μ Java. μ Java is a reduced model of JavaCard, dedicated to the study of the interaction of the source language, byte code, the byte code verifier and the compiler. In order to make the Isabelle sources more accessible, this introduction provides a brief survey of the main concepts of μ Java.

The μ Java **source language** (see Chapter 2) only comprises a part of the original JavaCard language. It models features such as:

- The basic “primitive types” of Java
- Object orientation, in particular classes, and relevant relations on classes (subclass, widening)
- Methods and method signatures
- Inheritance and overriding of methods, dynamic binding
- Representatives of “relevant” expressions and statements
- Generation and propagation of system exceptions

However, the following features are missing in μ Java wrt. JavaCard:

- Some primitive types (**byte**, **short**)
- Interfaces and related concepts, arrays
- Most numeric operations, syntactic variants of statements (**do-loop**, **for-loop**)
- Complex block structure, method bodies with multiple returns
- Abrupt termination (**break**, **continue**)
- Class and method modifiers (such as **static** and **public/private** access modifiers)
- User-defined exception classes and an explicit **throw**-statement. Exceptions cannot be caught.

- A “definite assignment” check

In addition, features are missing that are not part of the JavaCard language, such as multithreading and garbage collection. No attempt has been made to model peculiarities of JavaCard such as the applet firewall or the transaction mechanism.

For a more complete Isabelle model of JavaCard, the reader should consult the Bali formalization (<https://isabelle.in.tum.de/verificard/Bali/document.pdf>), which models most of the source language features of JavaCard, however without describing the bytecode level.

The central topics of the source language formalization are:

- Description of the structure of the “runtime environment”, in particular structure of classes and the program state
- Definition of syntax, typing rules and operational semantics of statements and expressions
- Definition of “conformity” (characterizing type safety) and a type safety proof

The μ Java **virtual machine** (see Chapter 3) corresponds rather directly to the source level, in the sense that the same data types are supported and bytecode instructions required for emulating the source level operations are provided. Again, only one representative of different variants of instructions has been selected; for example, there is only one comparison operator. The formalization of the bytecode level is purely descriptive (“no theorems”) and rather brief as compared to the source level; all questions related to type systems for and type correctness of bytecode are dealt with in chapter on bytecode verification.

The problem of **bytecode verification** (see Chapter 4) is dealt with in several stages:

- First, the notion of “method type” is introduced, which corresponds to the notion of “type” on the source level.
- Well-typedness of instructions wrt. a method type is defined (see Section 4.19). Roughly speaking, determining well-typedness is *type checking*.
- It is shown that bytecode that is well-typed in this sense can be safely executed – a type soundness proof on the bytecode level (Section 4.23).
- Given raw bytecode, one of the purposes of bytecode verification is to determine a method type that is well-typed according to the above definition. Roughly speaking, this is *type inference*. The Isabelle formalization presents bytecode verification as an instance of an abstract dataflow algorithm (Kildall’s algorithm, see Sections 4.8 to 4.25).

Bytecode verification in μ Java so far takes into account:

- Operations and branching instructions
- Exceptions

Initialization during object creation is not accounted for in the present document (see the formalization in <https://isabelle.in.tum.de/verificard/obj-init/document.pdf>), neither is the `jsr` instruction.

1.2 Theory Dependencies

Figure [1.1](#) shows the dependencies between the Isabelle theories in the following sections.

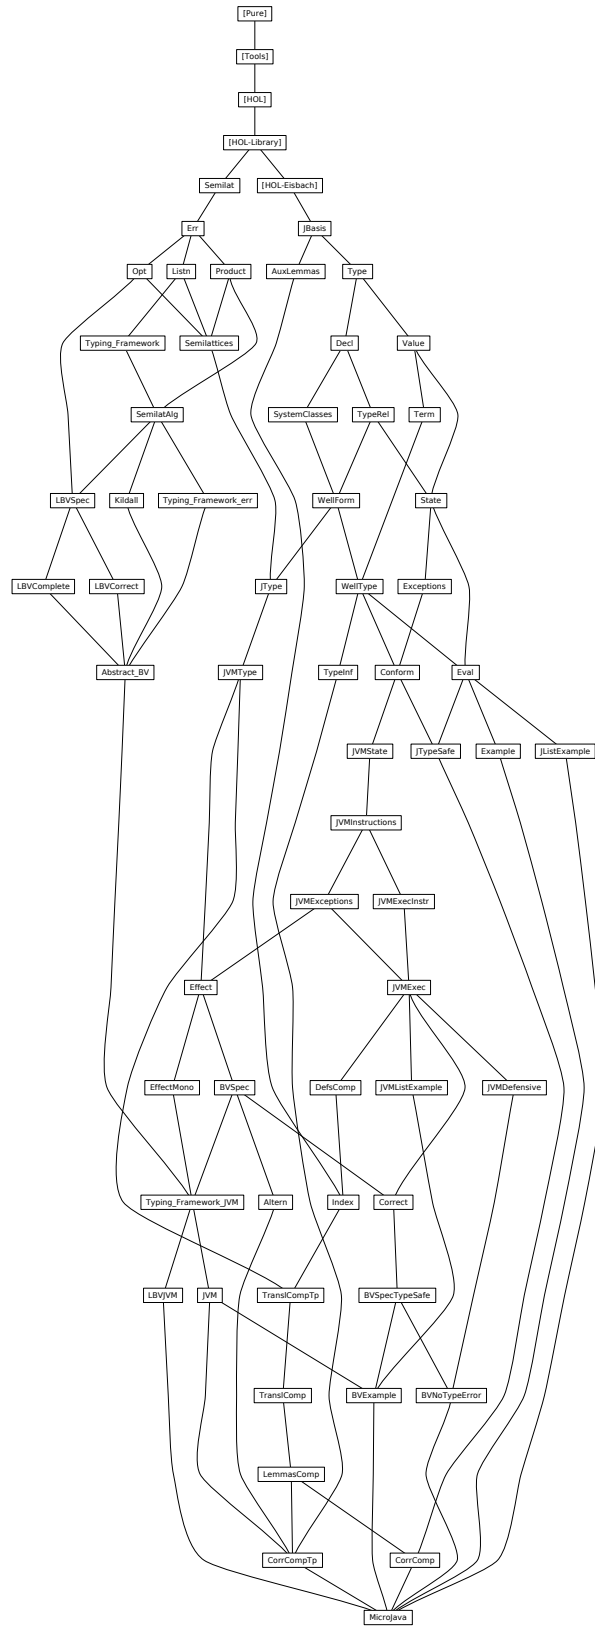

Figure 1.1: Theory Dependency Graph

Chapter 2

Java Source Language

2.1 Some Auxiliary Definitions

```
theory JBasis
imports
  Main
  "HOL-Library.Transitive_Closure_Table"
  "HOL-Eisbach.Eisbach"
begin

lemmas [simp] = Let_def
```

2.1.1 unique

```
definition unique :: "('a × 'b) list => bool" where
  "unique == distinct ∘ map fst"
```

```
lemma fst_in_set_lemma: "(x, y) ∈ set xys ⟹ x ∈ fst ` set xys"
  ⟨proof⟩
```

```
lemma unique_Nil [simp]: "unique []"
  ⟨proof⟩
```

```
lemma unique_Cons [simp]: "unique ((x,y)#l) = (unique l & (∀y. (x,y) ∉ set l))"
  ⟨proof⟩
```

```
lemma unique_append: "unique l' ⟹ unique l ⟹
  (∀ (x,y) ∈ set l. ∀ (x',y') ∈ set l'. x' ≠ x) ⟹ unique (l @ l')"
  ⟨proof⟩
```

```
lemma unique_map_inj: "unique l ⟹ inj f ⟹ unique (map (%(k,x). (f k, g k x)) l)"
  ⟨proof⟩
```

2.1.2 More about Maps

```
lemma map_of_SomeI: "unique l ⟹ (k, x) ∈ set l ⟹ map_of l k = Some x"
  ⟨proof⟩
```

```
lemma Ball_set_table: "(∀ (x,y) ∈ set l. P x y) ⟹ (∀ x. ∀ y. map_of l x = Some y ⟶ P
```

10

```
x y)"  
  ⟨proof⟩
```

```
lemma table_of_remap_SomeD:  
  "map_of (map (λ((k,k'),x). (k,(k',x))) t) k = Some (k',x) ==>  
    map_of t (k, k') = Some x"  
  ⟨proof⟩
```

end

2.2 Java types

theory *Type* imports *JBasis* begin

typeddecl *cnam*

instantiation *cnam* :: equal
begin

```
definition "HOL.equal (cn :: cnam) cn' ⟷ cn = cn'"  
instance ⟨proof⟩
```

end

These instantiations only ensure that the merge in theory *MicroJava* succeeds. FIXME

instantiation *cnam* :: typerep
begin

```
definition "typerep_class.typerep ≡ λ_ :: cnam itself. Typerep.Typerep (STR ''Type.cnam'')  
  []"  
instance ⟨proof⟩
```

end

instantiation *cnam* :: term_of
begin

```
definition "term_of_class.term_of (C :: cnam) ≡  
  Code_Evaluation.Const (STR ''dummy_cnam'') (Typerep.Typerep (STR ''Type.cnam'') [])"  
instance ⟨proof⟩
```

end

instantiation *cnam* :: partial_term_of
begin

```
definition "partial_term_of_class.partial_term_of (C :: cnam itself) n = undefined"  
instance ⟨proof⟩
```

end

— exceptions
datatype

```

    xcpt
    = NullPointer
    | ClassCast
    | OutOfMemory

— class names
datatype cname
  = Object
  | Xcpt xcpt
  | Cname cnam

typeddecl vnam — variable or field name

instantiation vnam :: equal
begin

definition "HOL.equal (vn :: vnam) vn'  $\longleftrightarrow$  vn = vn'"
instance <proof>

end

instantiation vnam :: typerep
begin

definition "typerep_class.typerep  $\equiv$   $\lambda\_ :: vnam$  itself. Typerep.Typerep (STR ''Type.vnam'')
  []"
instance <proof>

end

instantiation vnam :: term_of
begin

definition "term_of_class.term_of (V :: vnam)  $\equiv$ 
  Code_Evaluation.Const (STR ''dummy_vnam'') (Typerep.Typerep (STR ''Type.vnam'') [])"
instance <proof>

end

instantiation vnam :: partial_term_of
begin

definition "partial_term_of_class.partial_term_of (V :: vnam itself) n = undefined"
instance <proof>

end

typeddecl mname — method name

instantiation mname :: equal
begin

definition "HOL.equal (M :: mname) M'  $\longleftrightarrow$  M = M'"
instance <proof>

```

end

instantiation *mname* :: *typerep*
begin

definition "*typerep_class.typerep* $\equiv \lambda_ :: mname\ itself.\ Typerep.Typerep\ (STR\ \text{'Type.mname'})$
[]"

instance $\langle proof \rangle$

end

instantiation *mname* :: *term_of*
begin

definition "*term_of_class.term_of* (*M* :: *mname*) \equiv
Code_Evaluation.Const (STR 'dummy_mname') (Typerep.Typerep (STR 'Type.mname') [])"

instance $\langle proof \rangle$

end

instantiation *mname* :: *partial_term_of*
begin

definition "*partial_term_of_class.partial_term_of* (*M* :: *mname* *itself*) *n* = undefined"

instance $\langle proof \rangle$

end

— names for *This* pointer and local/field variables

datatype *vname*
= *This*
/ *VName vnam*

— primitive type, cf. 4.2

datatype *prim_ty*
= *Void* — 'result type' of void methods
/ *Boolean*
/ *Integer*

— reference type, cf. 4.3

datatype *ref_ty*

end

```

2.8 System Classes

theory *SystemClasses* imports *Decl* begin

This theory provides definitions for the *Object* class, and the system exceptions.

```

definition ObjectC :: "'c cdecl" where
  [code_unfold]: "ObjectC ≡ (Object, (undefined, [], []))"

```

```

definition NullPointerC :: "'c cdecl" where
  [code_unfold]: "NullPointerC ≡ (Xcpt NullPointer, (Object, [], []))"

```

```

definition ClassCastC :: "'c cdecl" where
  [code_unfold]: "ClassCastC ≡ (Xcpt ClassCast, (Object, [], []))"

```

```

definition OutOfMemoryC :: "'c cdecl" where
  [code_unfold]: "OutOfMemoryC ≡ (Xcpt OutOfMemory, (Object, [], []))"

```

```

definition SystemClasses :: "'c cdecl list" where
  [code_unfold]: "SystemClasses ≡ [ObjectC, NullPointerC, ClassCastC, OutOfMemoryC]"

```

end

2.9 Well-formedness of Java programs

```

theory WellForm
imports TypeRel SystemClasses
begin

```

for static checks on expressions and statements, see *WellType*.

improvements over Java Specification 1.0 (cf. 8.4.6.3, 8.4.6.4, 9.4.1):

- a method implementing or overwriting another method may have a result type that widens to the result type of the other method (instead of identical type)

simplifications:

- for uniformity, Object is assumed to be declared like any other class

```
type_synonym 'c wf_mb = "'c prog => cname => 'c mdecl => bool"
```

```
definition wf_syscls :: "'c prog => bool" where

2.10 Well-typedness Constraints

theory WellType imports Term WellForm begin

the formulation of well-typedness of method calls given below (as well as the Java Specification 1.0) is a little too restrictive: It does not allow methods of class Object to be called upon references of interface type.

simplifications:

- the type rules include all static checks on expressions and statements, e.g. definedness of names (of parameters, locals, fields, methods)

local variables, including method parameters and This:

```

type_synonym lenv = "vname → ty"
type_synonym 'c env = "'c prog × lenv"

```

```

abbreviation (input)
  prg :: "'c env => 'c prog"
  where "prg == fst"

```

```

abbreviation (input)
  localT :: "'c env => (vname → ty)"
  where "localT == snd"

```

```

definition more_spec :: "'c prog => (ty × 'x) × ty list => (ty × 'x) × ty list => bool"
  where "more_spec G == λ((d,h),pTs). λ((d',h'),pTs'). G ⊢ d ≤ d' ∧
    list_all2 (λT T'. G ⊢ T ≤ T') pTs pTs'"

```

```

definition appl_methds :: "'c prog => cname => sig => ((ty × ty) × ty list) set"
  — applicable methods, cf. 15.11.2.1

```

```

where "appl_methds G C ==  $\lambda(mn, pTs).$ 
      {((Class md,rT),pTs') | md rT mb pTs'.
       method (G,C) (mn, pTs') = Some (md,rT,mb)  $\wedge$ 
       list_all2 ( $\lambda T T'. G \vdash T \preceq T'$ ) pTs pTs'}"

definition max_spec :: "'c prog  $\Rightarrow$  cname  $\Rightarrow$  sig  $\Rightarrow$  ((ty  $\times$  ty)  $\times$  ty list) set"
  — maximally specific methods, cf. 15.11.2.2
  where "max_spec G C sig == {m. m  $\in$  appl_methds G C sig  $\wedge$ 
      ( $\forall m' \in$  appl_methds G C sig.
       more_spec G m' m  $\rightarrow$  m' = m)}"

2.14 Example MicroJava Program

```
theory Example imports SystemClasses Eval begin
```

The following example MicroJava program includes: class declarations with inheritance, hiding of fields, and overriding of methods (with refined result type), instance creation, local assignment, sequential composition, method call with dynamic binding, literal values, expression statement, local access, type cast, field assignment (in part), skip.

```

class Base {
  boolean vee;
  Base foo(Base x) {return x;}

```

```
}

```

```
class Ext extends Base {
  int vee;
  Ext foo(Base x) {((Ext)x).vee=1; return null;}
}

```

```
class Example {
  public static void main (String args[]) {
    Base e=new Ext();
    e.foo(null);
  }
}

```

```
datatype cnam' = Base' | Ext'
datatype vnam' = vee' | x' | e'

```

cnam' and *vnam'* are intended to be isomorphic to *cnam* and *vnam*

```

3.4 Exception handling in the JVM

theory JVMExceptions imports JVMInstructions begin

definition match_exception_entry :: "jvm_prog \Rightarrow cname \Rightarrow p_count \Rightarrow exception_entry \Rightarrow bool" where

"match_exception_entry G cn pc ee ==
 let (start_pc, end_pc, handler_pc, catch_type) = ee in
 start_pc \leq pc \wedge pc < end_pc \wedge G \vdash cn \preceq_C catch_type"

primrec match_exception_table :: "jvm_prog \Rightarrow cname \Rightarrow p_count \Rightarrow exception_table
 \Rightarrow p_count option"

where

"match_exception_table G cn pc [] = None"
 | "match_exception_table G cn pc (e#es) = (if match_exception_entry G cn pc e
 then Some (fst (snd (snd e)))
 else match_exception_table G cn pc es)"

abbreviation

ex_table_of :: "jvm_method \Rightarrow exception_table"
 where "ex_table_of m == snd (snd (snd m))"

primrec find_handler :: "jvm_prog \Rightarrow val option \Rightarrow aheap \Rightarrow frame list
 \Rightarrow jvm_state"

where

"find_handler G xcpt hp [] = (xcpt, hp, [])"
 | "find_handler G xcpt hp (fr#frs) =
 (case xcpt of
 None \Rightarrow (None, hp, fr#frs)
 | Some xc \Rightarrow
 let (stk, loc, C, sig, pc) = fr in
 (case match_exception_table G (cname_of hp xc) pc
 (ex_table_of (snd (snd (the (method (G, C) sig))))) of
 None \Rightarrow find_handler G (Some xc) hp frs
 | Some handler_pc \Rightarrow (None, hp, ([xc], loc, C, sig, handler_pc)#frs)))"

System exceptions are allocated in all heaps:

Only program counters that are mentioned in the exception table can be returned by *match_exception_table*:

lemma match_exception_table_in_et:

"match_exception_table G C pc et = Some pc' $\implies \exists e \in \text{set et. pc}' = \text{fst (snd (snd e))}"$
 <proof>

end

3.5 Program Execution in the JVM

theory JVMEExec imports JVMEExecInstr JVMExceptions begin

```

fun
  exec :: "jvm_prog × jvm_state => jvm_state option"
  — exec is not recursive. fun is just used for pattern matching
where

4.19 The Bytecode Verifier

```

theory BVSpec
imports Effect
begin

```

This theory contains a specification of the BV. The specification describes correct typings of method bodies; it corresponds to type *checking*.

definition

— The program counter will always be inside the method:

```

check_bounded :: "instr list ⇒ exception_table ⇒ bool" where
  "check_bounded ins et ⟷
    (∀ pc < length ins. ∀ pc' ∈ set (succs (ins!pc) pc). pc' < length ins) ∧
    (∀ e ∈ set et. fst (snd (snd e)) < length ins)"

```

definition

— The method type only contains declared classes:

```

check_types :: "jvm_prog ⇒ nat ⇒ nat ⇒ JVMType.state list ⇒ bool" where
  "check_types G mxs mxr phi ⟷ set phi ⊆ states G mxs mxr"

```

definition

— An instruction is welltyped if it is applicable and its effect
 — is compatible with the type at all successor instructions:

```

wt_instr :: "[instr,jvm_prog,ty,method_type,nat,p_count,
             exception_table,p_count] ⇒ bool" where
"wt_instr i G rT phi mxs max_pc et pc ⇔
app i G mxs rT pc et (phi!pc) ∧
(∀ (pc',s') ∈ set (eff i G pc et (phi!pc)). pc' < max_pc ∧ G ⊢ s' <= ' phi!pc')"
```

definition

— The type at pc=0 conforms to the method calling convention:

```

wt_start :: "[jvm_prog,cname,ty list,nat,method_type] ⇒ bool" where
"wt_start G C pTs mxl phi ⇔
G ⊢ Some ([],(OK (Class C))#(map OK pTs))@(replicate mxl Err) <= ' phi!0"
```

definition

— A method is welltyped if the body is not empty, if execution does not
 — leave the body, if the method type covers all instructions and mentions
 — declared classes only, if the method calling convention is respected, and
 — if all instructions are welltyped.

```

wt_method :: "[jvm_prog,cname,ty list,ty,nat,nat,instr list,
               exception_table,method_type] ⇒ bool" where
"wt_method G C pTs rT mxs mxl ins et phi ⇔
(let max_pc = length ins in
0 < max_pc ∧
length phi = length ins ∧
check_bounded ins et ∧
check_types G mxs (1+length pTs+mxl) (map OK phi) ∧
wt_start G C pTs mxl phi ∧
(∀ pc. pc < max_pc → wt_instr (ins!pc) G rT phi mxs max_pc et pc))"
```

definition

— A program is welltyped if it is wellformed and all methods are welltyped

```

wt_jvm_prog :: "[jvm_prog,prog_type] ⇒ bool" where
"wt_jvm_prog G phi ⇔
wf_prog (λG C (sig,rT,(maxs,maxl,b,et)).
wt_method G C (snd sig) rT maxs maxl b et (phi C sig)) G"
```

lemma check_boundedD:

```

"[[ check_bounded ins et; pc < length ins;
   (pc',s') ∈ set (eff (ins!pc) G pc et s) ]] ⇒
pc' < length ins"
⟨proof⟩
```

lemma wt_jvm_progD:

```

"wt_jvm_prog G phi ⇒ (∃ wt. wf_prog wt G)"
⟨proof⟩
```

lemma wt_jvm_prog_impl_wt_instr:

```

end

```

4.23 BV Type Safety Proof

```

theory BVSpecTypeSafe
imports Correct
begin

```

This theory contains proof that the specification of the bytecode verifier only admits type safe programs.

4.23.1 Preliminaries

Simp and intro setup for the type safety proof:

```
lemmas defs1 = sup_state_conv correct_state_def correct_frame_def
           wt_instr_def eff_def norm_eff_def
```

```
lemmas widen_rules[intro] = approx_val_widen approx_loc_widen approx_stk_widen
```

```
lemmas [simp del] = split_paired_All
```

If we have a welltyped program and a conforming state, we can directly infer that the current instruction is well typed:

```
lemma wt_jvm_prog_impl_wt_instr_cor:
  "[[ wt_jvm_prog G phi; method (G,C) sig = Some (C,rT,maxs,maxl,ins,et);
    G,phi ⊢JVM (None, hp, (stk,loc,C,sig,pc)#frs)√ ]]
  ⇒ wt_instr (ins!pc) G rT (phi C sig) maxs (length ins) et pc"
  <proof>
```

4.23.2 Exception Handling

Exceptions don't touch anything except the stack:

```
lemma exec_instr_xcpt:
  "(fst (exec_instr i G hp stk vars Cl sig pc frs) = Some xcp)
  = (∃stk'. exec_instr i G hp stk vars Cl sig pc frs =
    (Some xcp, hp, (stk', vars, Cl, sig, pc)#frs))"
  <proof>
```

Relates *match_any* from the Bytecode Verifier with *match_exception_table* from the operational semantics:

```
lemma in_match_any:
  "match_exception_table G xcpt pc et = Some pc' ⇒
  ∃C. C ∈ set (match_any G pc et) ∧ G ⊢ xcpt ≤C C ∧
  match_exception_table G C pc et = Some pc'"
  (is "PROP ?P et" is "?match et ⇒ ?match_any et")
  <proof>
```

```
lemma match_et_imp_match:
  "match_exception_table G (Xcpt X) pc et = Some handler
  ⇒ match G X pc et = [Xcpt X]"
  <proof>
```

We can prove separately that the recursive search for exception handlers (*find_handler*) in the frame stack results in a conforming state (if there was no matching exception handler in the current frame). We require that the exception is a valid heap address, and that the state before the exception occurred conforms.

```
lemma uncaught_xcpt_correct:
  "∧f. [[ wt_jvm_prog G phi; xcp = Addr adr; hp adr = Some T;
    G,phi ⊢JVM (None, hp, f#frs)√ ]]
  ⇒ G,phi ⊢JVM (find_handler G (Some xcp) hp frs)√"
  (is "∧f. [[ ?wt; ?adr; ?hp; ?correct (None, hp, f#frs) ]] ⇒ ?correct (?find frs)")
  <proof>
```

declare *raise_if_def* [simp]

The requirement of lemma *uncaught_xcpt_correct* (that the exception is a valid reference on the heap) is always met for welltyped instructions and conformant states:

```
lemma exec_instr_xcpt_hp:
  "[[ fst (exec_instr (ins!pc) G hp stk vars C1 sig pc frs) = Some xcp;
    wt_instr (ins!pc) G rT (phi C sig) maxs (length ins) et pc;
    G,phi ⊢JVM (None, hp, (stk,loc,C,sig,pc)#frs)√ ] ]
  ⇒ ∃adr T. xcp = Addr adr ∧ hp adr = Some T"
  (is "[[ ?xcpt; ?wt; ?correct ] ] ⇒ ?thesis")
  <proof>
```

```
lemma cname_of_xcp [intro]:
  "[[ preallocated hp; xcp = Addr (XcptRef x) ] ] ⇒ cname_of hp xcp = Xcpt x"
  <proof>
```

Finally we can state that, whenever an exception occurs, the resulting next state always conforms:

```
lemma xcpt_correct:
  "[[ wt_jvm_prog G phi;
    method (G,C) sig = Some (C,rT,maxs,maxl,ins,et);
    wt_instr (ins!pc) G rT (phi C sig) maxs (length ins) et pc;
    fst (exec_instr (ins!pc) G hp stk loc C sig pc frs) = Some xcp;
    Some state' = exec (G, None, hp, (stk,loc,C,sig,pc)#frs);
    G,phi ⊢JVM (None, hp, (stk,loc,C,sig,pc)#frs)√ ] ]
  ⇒ G,phi ⊢JVM state'√"
  <proof>
```

4.23.3 Single Instructions

In this section we look at each single (welltyped) instruction, and prove that the state after execution of the instruction still conforms. Since we have already handled exceptions above, we can now assume, that on exception occurs for this (single step) execution.

lemma isIntgI [intro, simp]: "G, hp \vdash v $:: \preceq$ PrimT Integer \implies isIntg v"

⟨proof⟩

lemma list_all2_approx:

"list_all2 (approx_val G hp) s (map OK S) = list_all2 (conf G hp) s S"
 ⟨proof⟩

lemma list_all2_conf_widen:

"wf_prog mb G \implies
 list_all2 (conf G hp) a b \implies
 list_all2 ($\lambda x y. G \vdash x \preceq y$) b c \implies
 list_all2 (conf G hp) a c"
 ⟨proof⟩

The main theorem: welltyped programs do not produce type errors if they are started in a conformant state.

theorem no_type_error:

assumes welltyped: "wt_jvm_prog G Phi" and conforms: "G, Phi $\vdash_{JVM} s \checkmark$ "
 shows "exec_d G (Normal s) \neq TypeError"
 ⟨proof⟩

The theorem above tells us that, in welltyped programs, the defensive machine reaches the same result as the aggressive one (after arbitrarily many steps).

theorem welltyped_aggressive_imp_defensive:

"wt_jvm_prog G Phi $\implies G, \text{Phi} \vdash_{JVM} s \checkmark \implies G \vdash s \text{--jvm} \rightarrow t$
 $\implies G \vdash (\text{Normal } s) \text{--jvmd} \rightarrow (\text{Normal } t)"$
 ⟨proof⟩

lemma neq_TypeError_eq [simp]: "s \neq TypeError = ($\exists s'. s = \text{Normal } s'$)"

⟨proof⟩

theorem no_type_errors:

"wt_jvm_prog G Phi $\implies G, \text{Phi} \vdash_{JVM} s \checkmark$
 $\implies G \vdash (\text{Normal } s) \text{--jvmd} \rightarrow t \implies t \neq \text{TypeError}"$
 ⟨proof⟩

corollary no_type_errors_initial:

fixes G ($\langle \Gamma \rangle$) and Phi ($\langle \Phi \rangle$)
 assumes wt: "wt_jvm_prog $\Gamma \Phi$ "
 assumes is_class: "is_class ΓC "
 and "method": "method (Γ, C) (m, []) = Some (C, b)"
 and m: "m \neq init"
 defines start: "s \equiv start_state $\Gamma C m$ "

assumes s: " $\Gamma \vdash (\text{Normal } s) \text{--jvmd} \rightarrow t$ "
 shows "t \neq TypeError"

⟨proof⟩

As corollary we get that the aggressive and the defensive machine are equivalent for welltyped programs (if started in a conformant state or in the canonical start state)

corollary welltyped_commutes:

fixes G ($\langle \Gamma \rangle$) and Phi ($\langle \Phi \rangle$)
 assumes wt: "wt_jvm_prog $\Gamma \Phi$ " and *: " $\Gamma, \Phi \vdash_{JVM} s \checkmark$ "
 shows " $\Gamma \vdash (\text{Normal } s) \text{--jvmd} \rightarrow (\text{Normal } t) = \Gamma \vdash s \text{--jvm} \rightarrow t$ "
 ⟨proof⟩

```

corollary welltyped_initial_commutates:
  fixes G (<Γ>) and Phi (<Φ>)
  assumes wt: "wt_jvm_prog Γ Φ"
  assumes is_class: "is_class Γ C"
    and "method": "method (Γ,C) (m,[]) = Some (C, b)"
    and m: "m ≠ init"
  defines start: "s ≡ start_state Γ C m"
  shows "Γ ⊢ (Normal s) -jvmd→ (Normal t) = Γ ⊢ s -jvm→ t"
  <proof>

end

```

4.25 Kildall for the JVM

```

<proof>

end

```

4.26 Example Welltypings

```

theory BVExample
imports
  "../JVM/JVMListExample"
  BVSpecTypeSafe
  JVM
begin

```

This theory shows type correctness of the example program in section 3.6 (p. 56) by explicitly providing a welltyping. It also shows that the start state of the program conforms to the welltyping; hence type safe execution is guaranteed.

4.26.1 Setup

Abbreviations for definitions we will have to use often in the proofs below:

```

lemmas name_defs    = list_name_def test_name_def val_name_def next_name_def
lemmas system_defs  = SystemClasses_def ObjectC_def NullPointerC_def
                      OutOfMemoryC_def ClassCastC_def
lemmas class_defs   = list_class_def test_class_def

```

These auxiliary proofs are for efficiency: class lookup, subclass relation, method and field lookup are computed only once:

```

lemma class_Object [simp]:
  "class E Object = Some (undefined, [], [])"
<proof>

```

```
lemma class_NullPointer [simp]:
  "class E (Xcpt NullPointer) = Some (Object, [], [])"
  <proof>
```

```
lemma class_OutOfMemory [simp]:
  "class E (Xcpt OutOfMemory) = Some (Object, [], [])"
  <proof>
```

```
lemma class_ClassCast [simp]:
  "class E (Xcpt ClassCast) = Some (Object, [], [])"
  <proof>
```

```
lemma class_list [simp]:
  "class E list_name = Some list_class"
  <proof>
```

```
lemma class_test [simp]:
  "class E test_name = Some test_class"
  <proof>
```

```
lemma E_classes [simp]:
  "{C. is_class E C} = {list_name, test_name, Xcpt NullPointer,
                        Xcpt ClassCast, Xcpt OutOfMemory, Object}"
  <proof>
```

The subclass relation spelled out:

```
lemma subcls1:
  "subcls1 E = {(list_name, Object), (test_name, Object), (Xcpt NullPointer, Object),
                (Xcpt ClassCast, Object), (Xcpt OutOfMemory, Object)}"
  <proof>
```

The subclass relation is acyclic; hence its converse is well founded:

```
lemma notin_rtrancl:
  "(a, b) ∈ r* ⇒ a ≠ b ⇒ (∧y. (a, y) ∉ r) ⇒ False"
  <proof>
```

```
lemma acyclic_subcls1_E: "acyclic (subcls1 E)"
  <proof>
```

```
lemma wf_subcls1_E: "wf ((subcls1 E)-1)"
  <proof>
```

Method and field lookup:

```
lemma method_Object [simp]:
  "method (E, Object) = Map.empty"
  <proof>
```

```
lemma method_append [simp]:
  "method (E, list_name) (append_name, [Class list_name]) =
   Some (list_name, PrimT Void, 3, 0, append_ins, [(1, 2, 8, Xcpt NullPointer)])"
  <proof>
```

```
lemma method_makelist [simp]:
```

```

"method (E, test_name) (makelist_name, []) =
Some (test_name, PrimT Void, 3, 2, make_list_ins, [])"
⟨proof⟩

lemma field_val [simp]:
  "field (E, list_name) val_name = Some (list_name, PrimT Integer)"
  ⟨proof⟩

lemma field_next [simp]:
  "field (E, list_name) next_name = Some (list_name, Class list_name)"
  ⟨proof⟩

lemma [simp]: "fields (E, Object) = []"
  ⟨proof⟩

lemma [simp]: "fields (E, Xcpt NullPointer) = []"
  ⟨proof⟩

lemma [simp]: "fields (E, Xcpt ClassCast) = []"
  ⟨proof⟩

lemma [simp]: "fields (E, Xcpt OutOfMemory) = []"
  ⟨proof⟩

lemma [simp]: "fields (E, test_name) = []"
  ⟨proof⟩

lemmas [simp] = is_class_def

```

The next definition and three proof rules implement an algorithm to enumerate natural numbers. The command `apply (elim pc_end pc_next pc_0` transforms a goal of the form

$$pc < n \implies P \ pc$$

into a series of goals

$$P \ 0$$

$$P \ (Suc \ 0)$$

...

$$P \ n$$

```

definition intervall :: "nat  $\Rightarrow$  nat  $\Rightarrow$  nat  $\Rightarrow$  bool" (<_  $\in$  [_, _']>) where
  "x  $\in$  [a, b)  $\equiv$  a  $\leq$  x  $\wedge$  x < b"

```

```

lemma pc_0: "x < n  $\implies$  (x  $\in$  [0, n)  $\implies$  P x)  $\implies$  P x"
  ⟨proof⟩

```

```

lemma pc_next: "x  $\in$  [n0, n)  $\implies$  P n0  $\implies$  (x  $\in$  [Suc n0, n)  $\implies$  P x)  $\implies$  P x"
  ⟨proof⟩

```

```

lemma pc_end: "x  $\in$  [n,n)  $\implies$  P x"
  ⟨proof⟩

```

4.26.2 Program structure

The program is structurally wellformed:

```
lemma wf_struct:
  "wf_prog (λG C mb. True) E" (is "wf_prog ?mb E")
  <proof>
```

4.26.3 Welltypings

We show welltypings of the methods `append_name` in class `list_name`, and `makelist_name` in class `test_name`:

```
lemmas eff_simps [simp] = eff_def norm_eff_def xcpt_eff_def
declare appInvoke [simp del]
```

```
definition phi_append :: method_type (<φa>) where
  "φa ≡ map (λ(x,y). Some (x, map OK y)) [
    (
      [], [Class list_name, Class list_name]),
    (
      [Class list_name], [Class list_name, Class list_name]),
    (
      [Class list_name], [Class list_name, Class list_name]),
    (
      [Class list_name, Class list_name], [Class list_name, Class list_name]),
    ([NT, Class list_name, Class list_name], [Class list_name, Class list_name]),
    (
      [Class list_name], [Class list_name, Class list_name]),
    (
      [Class list_name, Class list_name], [Class list_name, Class list_name]),
    (
      [PrimT Void], [Class list_name, Class list_name]),
    (
      [Class Object], [Class list_name, Class list_name]),
    (
      [], [Class list_name, Class list_name]),
    (
