10.31 The Volume of an n-Dimensional Ball

theory *Ball_Volume*
imports *Gamma_Function Lebesgue_Integral_Substitution*
begin

We define the volume of the unit ball in terms of the Gamma function. Note that the dimension need not be an integer; we also allow fractional dimensions, although we do not use this case or prove anything about it for now.

definition *unit_ball_vol* :: *real* ⇒ *real* **where**
unit_ball_vol n = *pi powr* (*n* / *2*) / *Gamma* (*n* / *2* + *1*)

lemma *unit_ball_vol_pos* [*simp*]: *n* ≥ *0* ⟹ *unit_ball_vol n* > *0*
by (*force simp*: *unit_ball_vol_def intro*: *divide_nonneg_pos*)

lemma *unit_ball_vol_nonneg* [*simp*]: *n* ≥ *0* ⟹ *unit_ball_vol n* ≥ *0*
by (*simp add*: *dual_order.strict_implies_order*)

We first need the value of the following integral, which is at the core of computing the measure of an *n* + *1*-dimensional ball in terms of the measure of an *n*-dimensional one.

lemma *emeasure_cball_aux_integral*:
(∫⁺*x*. *indicator* {−*1*..*1*} *x* ∗ *sqrt* (*1* − *x*²) ^ *n* ∂*lborel*) =

lemma real_sqrt_le_iff': x ≥ 0 ⟹ y ≥ 0 ⟹ sqrt x ≤ y ⟷ x ≤ y ^ 2
  using real_le_lsqrt sqrt_le_D by blast
```

Isabelle's type system makes it very difficult to do an induction over the dimension of a Euclidean space type, because the type would change in the inductive step. To avoid this problem, we instead formulate the problem in a more concrete way by unfolding the definition of the Euclidean norm.

```

10.32 Integral Test for Summability

theory *Integral_Test*
imports *Henstock_Kurzweil_Integration*
begin

The integral test for summability. We show here that for a decreasing non-negative function, the infinite sum over that function evaluated at the natural numbers converges iff the corresponding integral converges.

As a useful side result, we also provide some results on the difference between the integral and the partial sum. (This is useful e.g. for the definition of the Euler-Mascheroni constant)

10.33 Embedding Measure Spaces with a Function

```
theory Embed_Measure
imports Binary_Product_Measure
begin
```

Given a measure space on some carrier set Ω and a function f, we can define a push-forward measure on the carrier set $f(\Omega)$ whose σ-algebra is the one generated by mapping f over the original sigma algebra.

This is useful e. g. when f is injective, i. e. it is some kind of "tagging" function. For instance, suppose we have some algebraaic datatype of values with various constructors, including a constructor *RealVal* for real numbers. Then *embed_measure* allows us to lift a measure on real numbers to the appropriate subset of that algebraic datatype.

```
definition embed_measure :: 'a measure ⇒ ('a ⇒ 'b) ⇒ 'b measure where
  embed_measure M f = measure_of (f ‘ space M) {f ‘ A |A. A ∈ sets M}
                        (λA. emeasure M (f −‘ A ∩ space M))

10.37.11 Convergence criteria: especially uniform convergence of infinite products

Cauchy's criterion for the convergence of infinite products, adapted to proving uniform convergence: let $f_k(x)$ be a sequence of functions such that

1. $f_k(x)$ has uniformly bounded partial products, i.e. there exists a constant C such that $\prod_{k=0}^{m} f_k(x) \leq C$ for all m and $x \in A$.

2. For any $\varepsilon > 0$ there exists a number $M \in \mathbb{N}$ such that, for any $m, n \geq M$ and all $x \in A$ we have $|(\prod_{k=m}^{n} f_k(x)) - 1| < \varepsilon$

Then $\prod_{k=0}^{n} f_k(x)$ converges to $\prod_{k=0}^{\infty} f_k(x)$ uniformly for all $x \in A$.

lemma *uniformly_convergent_prod_Cauchy*:
fixes $f :: nat \Rightarrow 'a :: topological_space \Rightarrow 'b :: \{real_normed_div_algebra, comm_ring_1, banach\}$
assumes C: $\bigwedge x\ m.\ x \in A \Longrightarrow norm\ (\prod k{<}m.\ f\ k\ x) \leq C$
assumes $\bigwedge e.\ e > 0 \Longrightarrow \exists M.\ \forall x{\in}A.\ \forall m{\geq}M.\ \forall n{\geq}m.\ dist\ (\prod k{=}m..n.\ f\ k\ x)\ 1 < e$
shows *uniformly_convergent_on A* $(\lambda N\ x.\ \prod n{<}N.\ f\ n\ x)$
proof (*rule Cauchy_uniformly_convergent*, *rule uniformly_Cauchy_onI'*)
fix $\varepsilon :: real$ **assume** ε: $\varepsilon > 0$

theory Infinite_Product
  imports Infinite_Products

begin
```

The recurring theme of the whole development: the sum theory works be-

cause addition is uniformly continuous on *UNIV* (one uniformity entourage is invariant under translation by any constant). Multiplication is not, so the sum proofs cannot be ported verbatim. It is, however, uniformly continuous away from 0, and in a product with a non-zero value almost all subproducts lie near 1.

10.38.2 Subsets

For sums, unordered summability on A passes to every subset of A (*summable_on_subset_banach*). For products the corresponding statement with only the side condition $f\ x \neq 0$ for $x \in A - B$ is *false*, and no strengthening of the type class helps. A counterexample already exists over *real*: take the index type $bool \times nat$, let $A = UNIV$ and let B be the *True* half, and put $f\ p = (if\ fst\ p\ then\ -1\ else\ 1\ /\ (2::'a))$. The factors $1/2$ force the partial products over A to tend to 0, so f is multipliable on A, and f is non-zero everywhere; but over B the partial products are 1 and -1 alternately, so f is not multipliable on B.

The obstruction is a product equal to 0: it lets the partial products shrink to 0 along A while oscillating along B. Excluding it – that is, assuming a *non-zero* product, equivalently strong multipliability – makes the subset principle true, and that is what we prove here. The engine is the multiplicative Cauchy criterion *has_setprod_prods_near_1*: multiplication is not uniformly continuous on all of *UNIV*, which is why the additive proof cannot be transferred, but it is uniformly continuous away from 0, and for a non-zero product all the far-out subproducts live near 1.

The multiplicative Cauchy criterion: if the product over M converges to a non-zero limit then, outside a suitable finite set, *every* finite subproduct is close to 1. This strengthens *has_setprod_factors_tend_to_1* below, which is the special case of singleton subproducts.

Metric "splitting lemma" for products, the multiplicative replacement for the uniformity machinery of *prod_uniformity*: a finite product is Lipschitz in its factors, PROVIDED the factors stay bounded. (Multiplication is uniformly continuous on bounded sets, which is enough here – the factors that occur are partial products near the nonzero limits.)

using *assms* **by** *auto*

These are the variants that do *not* assume multipliability of each fibre but derive it. This needs more than multipliability of the whole family: it needs the product to be non-zero (see *has_setprod_subset_nonzero* and the counterexample discussed there). Note that a non-zero product also implies that no factor vanishes, so this replaces – rather than adds to – the former pointwise non-vanishing hypothesis.

Could the hypothesis $1 \leq f\ x$ could be replaced by strong multipliability together with $0 \leq f\ x$? It cannot: that statement is FALSE. Take $A = UNIV$ and $f = (\lambda k.\ 1 - 1\ /\ (2::'a)^{k\ +\ 2})$. Every factor is positive and $\sum_k 2^{-(k+2)}$ converges, so this f is strongly multipliable with a positive value L; but every factor is smaller than 1, so $L < 3/4 = prod\ f\ \{0\}$ and the inequality goes the wrong way. Factors below 1 shrink the product, and monotonicity of the partial products is precisely what the conclusion needs.

What can be weakened is where the hypothesis is required: only the factors OUTSIDE F need to be at least 1, those inside merely non-negative. That covers a product with finitely many small factors, which is the case that occurs in practice.

```

The types *ennreal*, *ereal*, and *enat* cannot be used with the infinite-product framework ((*multipliable_on*), (*has_setprod*), *infprod*) because it requires *semidom*, which demands additive cancellation. These types fail cancellation: e.g. $\infty + 1 = \infty + 2$ but $1 \neq 2$. Supporting them would require weakening the type class constraints on the framework definitions.

Restricting a product to one fibre again needs a non-zero product: for a family that is merely multipliable this fails, even when all the factors off the fibre are non-zero. (Take $A = \{True, False\}$, both fibres $UNIV$, $f\ True\ b = -1$ and $f\ False\ b = 1/2$: the whole family is multipliable with product 0, but the fibre over $True$ is not multipliable.)

f multipliable_on $(A \times B) \longleftrightarrow$ $(\lambda(x,y).\ f\ (y,x))$ *multipliable_on* $(B \times A)$
by (*metis has_setprod_swap multipliable_on_def*)

Not lemmas. For $c \neq 0$, neither $((\lambda x.\ c * f\ x)$ *has_setprod S*$)$ *A* nor $((\lambda x.\ f\ x * c)$ *has_setprod S*$)$ *A* is equivalent to (*f has_setprod S* / *c*) *A*: scaling every factor scales the product by $c^{card\ A}$, not by *c*. Counterexample: for $A = \{1, 2\}$, $f = (\lambda_.\ 1)$ and $c = 2$ the scaled product is 4, while the product of *f* is 1 and *S* / *c* is 2.

Fubini for absolute multipliability. The criterion below replaces an earlier *multipliable_on_SigmaI* whose hypotheses were $1 \le f\ (x, y)$ together with the order classes *conditionally_complete_linorder* and *linordered_idom*. Those were not arbitrary – they are the multiplicative transcription of the library's own *summable_on_SigmaI*, which assumes $0 \le f\ (x, y)$ and proves summability through a supremum – but products admit a route that sums do not: absolute multipliability is *summability of the norms of the deviations from 1* (*abs_multipliable_on_iff_summable_on*), so the whole question can be handed to *abs_summable_on_Sigma_iff* in *HOL−Analysis.Infinite_Sum*. That needs no order at all, only a Banach algebra, and it gives an iff rather than one implication.

Nothing is lost over the reals: for a family with $1 \le f\ x$ one has $1 + norm\ (f\ x - 1) = f\ x$, so multipliability and absolute multipliability coincide there. The hypotheses have a different shape, though – summability of the fibre sums $\sum_\infty y{\in}B\ x.\ norm\ (f\ (x, y) - 1)$ in place of multipliability of the fibre products – and the equivalence of the two shapes is not proved here.

lemma *abs_multipliable_on_Sigma_iff*:
 fixes $f :: 'a \times 'b \Rightarrow 'c :: \{banach, real_normed_algebra_1\}$

shows *f abs_multipliable_on Sigma A B* $\longleftrightarrow$
$(\forall x{\in}A.\ (\lambda y.\ f\ (x,\ y))\ abs_multipliable_on\ B\ x) \wedge$
$((\lambda x.\ \sum_\infty y{\in}B\ x.\ norm\ (f\ (x,\ y) - 1))\ summable_on\ A)$
— **NB** *summable_on_iff_abs_summable_on_real* must never be given to the simplifier: it rewrites *f summable_on A* to $(\lambda x.\ norm\ (f\ x))$ *summable_on A*, which matches itself again. Hence the explicit calculation below.
proof −

10.38.6 Complex numbers

A criterion that is useful when one controls the finite *partial sums* rather than the individual summands: if all of them are bounded, the family is absolutely summable. Splitting a finite subset according to the sign of g turns a bound on $|sum\ g\ D|$ into a bound on $\sum x{\in}D.\ |g\ x|$, and then *non-neg_bdd_above_summable_on* applies.

lemma *sum_abs_le_of_bdd_partial_sums*:
fixes $g :: 'a \Rightarrow real$
assumes *bdd*: $\bigwedge E.\ finite\ E \Longrightarrow E \subseteq A \Longrightarrow |sum\ g\ E| \leq C$

The logarithm of an unordered product. There is no unconditional complex analogue of *has_prod_imp_sums_ln_real*: $((\lambda x.\ Ln\ (f\ x))\ has_sum\ Ln\ P)\ A$ already fails on a two-element index set. Take $A = \{1, 2\}$ and $f = (\lambda_.\ -1)$; then $P = 1$ is non-zero with $Ln\ P = 0$, whereas $Ln\ (-1) =$ i $*$ *complex_of_real pi* and the sum is $2 *$ i $*$ *complex_of_real pi*. Factors far from 1 wrap the branch.

What is true is the statement under a hypothesis that rules the wrapping out, and every product with a non-zero value satisfies that hypothesis once a finite set of factors is removed. The first lemma isolates the additivity of *Ln*, which was previously buried in the proof of *strongly_multipliable_on_iff_abs_multipliable_on_complex*

below.

```

With additivity available, the logarithm of the product is the sum of the logarithms: the partial sums are literally *Ln (prod f X)*, and the limit is off the branch cut because the closed ball *cball 1 (1 / 2)* is, so *tendsto_Ln* applies.

```

The complex analogue of *strongly_multipliable_on_iff_abs_multipliable_on_real*. The difficulty anticipated in the original note – that $\sum x.\ Ln\ (f\ x)$ might cross branch cuts, with an ill-defined winding count for an unordered index set – does not in fact arise. A non-zero product forces every finite subproduct outside a suitable finite set to lie within *1/2* of *1*, and *Ln_prod_of_prods_near_1* above turns that into exact additivity of *Ln*. The resulting partial sums of $Ln \circ f$ are then bounded by *norm_Ln_le*, which gives absolute summability and hence absolute multipliability.

lemma *strongly_multipliable_on_iff_abs_multipliable_on_complex*:
  fixes f :: ‹$'a \Rightarrow complex$›

```

A striking consequence, for real and for complex families: an unordered product whose value is non-zero converges *absolutely*. So for these types there is no distinction between unconditional and absolute convergence of products once the value *0* is excluded – the exact analogue of the corresponding fact for sums.

The following theorem relates (*abs_summable_on*) with *Infinite_Sum.abs_summable_on*. Note that while this theorem expresses an equivalence, the notion on the lhs is more general nonetheless because it applies to a wider range of types. (The

rhs requires second-countable Banach spaces while the lhs is well-defined on arbitrary real vector spaces.)

 Continuous_Extension
begin
```

Absolute retracts (AR), absolute neighbourhood retracts (ANR) and also

Euclidean neighbourhood retracts (ENR). We define AR and ANR by specializing the standard definitions for a set to embedding in spaces of higher dimension.

John Harrison writes: "This turns out to be sufficient (since any set in $\mathbb{R}^n$ can be embedded as a closed subset of a convex subset of $\mathbb{R}^{n+1}$) to derive the usual definitions, but we need to split them into two implications because of the lack of type quantifiers. Then ENR turns out to be equivalent to ANR plus local compactness."

definition *AR* :: *'a::topological_space set* ⇒ *bool* **where**
AR S ≡ ∀ *U*. ∀ *S'*::(*'a* ∗ *real*) *set*.
S homeomorphic S' ∧ *closedin* (*top_of_set U*) *S'* ⟶ *S' retract_of U*

definition *ANR* :: *'a::topological_space set* ⇒ *bool* **where**
ANR S ≡ ∀ *U*. ∀ *S'*::(*'a* ∗ *real*) *set*.
S homeomorphic S' ∧ *closedin* (*top_of_set U*) *S'*
⟶ (∃ *T*. *openin* (*top_of_set U*) *T* ∧ *S' retract_of T*)

definition *ENR* :: *'a::topological_space set* ⇒ *bool* **where**
ENR S ≡ ∃ *U*. *open U* ∧ *S retract_of U*

First, show that we do indeed get the "usual" properties of ARs and ANRs.

10.42.8 The complement of a set and path-connectedness

Complement in dimension N > 1 of set homeomorphic to any interval in any dimension is (path-)connected. This naively generalizes the argument in Ryuji Maehara's paper "The Jordan curve theorem via the Brouwer fixed point theorem", American Mathematical Monthly 1984.

lemma *unbounded_components_complement_absolute_retract*:

10.43.12 Upper and lower hemicontinuous functions

And relation in the case of preimage map to open and closed maps, and fact that upper and lower hemicontinuity together imply continuity in the sense of the Hausdorff metric (at points where the function gives a bounded and nonempty set).

Many similar proofs below.

10.47.2 Determinants of linear functions between Euclidean spaces

det is the determinant of a square matrix. In the following, we define the equivalent notion of the determinant of an endomorphism (in a finite-dimensional vector space).

abbreviation *matrix_det* :: (('*a* :: *comm_ring_1*, '*b* :: *finite*) *vec*, '*b*) *vec* ⇒ '*a*
where *matrix_det* ≡ *Determinants.det*

lemmas *matrix_det_def* = *Determinants.det_def*

10.47.3 Absolute determinant of a multiset

For the "normal" determinant of a list of vectors, the order of the vectors matters insofar as it determines the sign. If we look at the absolute value of the determinant, however, the order does not matter and we can therefore define the absolute determinant of a (finite) multiset of vectors.

This can e.g. be useful to check whether a multiset of vectors is dependent or not.

```
definition abs_det :: ('a :: euclidean_space) multiset ⇒ real where
  abs_det X = (if size X ≠ DIM('a) then 0

10.51 Convergence of Formal Power Series

theory *FPS_Convergence*
imports
Generalised_Binomial_Theorem
HOL−Computational_Algebra.Formal_Power_Series
HOL−Computational_Algebra.Polynomial_FPS

begin

In this theory, we will connect formal power series (which are algebraic objects) with analytic functions. This will become more important in complex analysis, and indeed some of the less trivial results will only be proven there.

10.51.6 Power series expansions of analytic functions

This predicate contains the notion that the given formal power series converges in some disc of positive radius around the origin and is equal to the given complex function there.

This relationship is unique in the sense that no complex function can have more than one formal power series to which it expands, and if two holomorphic functions that are holomorphic on a connected open set around the origin and have the same power series expansion, they must be equal on that set.

More concrete statements about the radius of convergence can usually be made, but for many purposes, the statment that the series converges to the function in some neighbourhood of the origin is enough, and that can be shown almost fully automatically in most cases, as there are straightforward introduction rules to show this.

In particular, when one wants to relate the coefficients of the power series to the values of the derivatives of the function at the origin, or if one wants to approximate the coefficients of the series with the singularities of the function, this predicate is enough.
