9.12.24 Nowhere-dense zeros in one dimension

On a connected open set, the zero set of a real-analytic function that is not identically zero is nowhere dense. In one dimension, the set where all derivatives vanish is clopen; the multivariate case reduces to this via one-dimensional slices.

If all derivatives vanish at a point, the function vanishes on its Taylor ball there.

The inverse and implicit function theorems for real-analytic maps (*real_analytic_local_inverse*, *real_analytic_implicit_function*) build on this theory.

9.13 A C^∞ Function That Is Not Analytic

The flat function $x \mapsto exp\ (-1/x)$ for $x > 0$, 0 otherwise, is C^∞ on $\mathbb{R}$. All of its derivatives vanish at 0, while the function is positive to the right of 0; so it is not real-analytic at 0. This witnesses $C^\omega \neq C^\infty$.

```
definition exp_bump :: real ⇒ real where
  exp_bump x = (if 0 < x then exp (− (1 / x)) else 0)
```

9.13.1 Derivatives of the flat function

Every derivative of *exp_bump* has the form $x \mapsto p\ (1/x) * exp\ (-1/x)$ for $x > 0$ and vanishes for $x \leq 0$, where p is a real polynomial function. The key estimate is that $p\ (1/x) * exp\ (-1/x) \longrightarrow 0$ as $x \longrightarrow 0^+$.

```

9.14 The formal-series local inverse of a real-analytic map (majorant method)

For a real-analytic self-map f of a Euclidean space with $f\ 0 = 0$ and $Df(0) = id$, we construct a convergent power series h with $f\ (h\ y) = y$ near 0. Writing $f = id - \varphi$, the coefficients of h are determined degree by degree by $h\ y = y + \varphi\ (h\ y)$ (*ra_inverse_coeffs*); a bootstrap argument in the style of Gouëzel bounds them by a convergent majorant.

9.15 The real-analytic inverse function theorem

A real-analytic map between Euclidean spaces whose derivative at a point is bijective has a real-analytic local inverse. The C^1 inverse function theorem of HOL-Analysis provides the inverse; the majorant method of *Real_Analytic_Inverse* shows that it is real-analytic.

```

9.16 The real-analytic implicit function theorem

If F is real-analytic near $(x0,\ y0)$, $F\ (x0,\ y0) = 0$ and the partial derivative of F in its second argument at $(x0,\ y0)$ is bijective, then near $x0$ there is a real-analytic g with $g\ x0 = y0$ and $F\ (x,\ g\ x) = 0$.

Proof: apply the real-analytic inverse function theorem to $\Phi\ (x,\ y) = (x,\ F\ (x,\ y))$ and read off the solution from the second component of the local inverse.

```
theorem real_analytic_implicit_function:

```

Bounded variation and vector variation for functions *real ⇒ 'a*, following HOL Light's *Multivariate/integration.ml*.

HOL Light works with *real^1 ⇒ real^N* and defines bounded variation via set variation of the increment function. We adapt this to Isabelle's *real* domain directly.

9.17 Set variation

```
definition set_variation :: real set ⇒ (real set ⇒ 'a::euclidean_space) ⇒ real

The next lemma is a variant of *density_unique*. Note that it uses the notation for nonnegative set integrals introduced earlier.

lemma (**in** *sigma_finite_measure*) *density_unique2*:
assumes [*measurable*]: $f \in borel_measurable\ M\ f' \in borel_measurable\ M$
assumes *density_eq*: $\bigwedge A.\ A \in sets\ M \Longrightarrow (\int^+ x \in A.\ f\ x\ \partial M) = (\int^+ x \in A.\ f'\ x\ \partial M)$
shows $AE\ x\ in\ M.\ f\ x = f'\ x$
proof (*rule density_unique*)
show $density\ M\ f = density\ M\ f'$
by (*intro measure_eqI*) (*auto simp*: *emeasure_density intro*!: *density_eq*)
qed (*auto simp add*: *assms*)

The next lemma implies the same statement for Banach-space valued functions using Hahn-Banach theorem and linear forms. Since they are not yet

easily available, I only formulate it for real-valued functions.

lemma *density_unique_real*:
fixes $f\ f'$::_ ⇒ *real*
assumes *M*[*measurable*]: *integrable M f integrable M f'*
assumes *density_eq*: $\bigwedge A.\ A \in sets\ M \Longrightarrow (\int x \in A.\ f\ x\ \partial M) = (\int x \in A.\ f'\ x\ \partial M)$
shows *AE x in M. f x = f' x*
proof −

10.5 Scheffé's lemma

The next lemma shows that L^1 convergence of a sequence of functions follows from almost everywhere convergence and the weaker condition of the convergence of the integrated norms (or even just the nontrivial inequality about them). Useful in a lot of contexts! This statement (or its variations) are known as Scheffe lemma.

The formalization is more painful as one should jump back and forth between reals and ereals and justify all the time positivity or integrability (thankfully, measurability is handled more or less automatically).

proposition *Scheffe_lemma1*:
assumes $\bigwedge n.$ *integrable M (F n) integrable M f*
AE x in M. $(\lambda n.\ F\ n\ x) \longrightarrow f\ x$

10.7.4 Averaging Theorem

We aim to lift results from the real case to arbitrary Banach spaces. Our fundamental tool in this regard will be the averaging theorem. The proof of this theorem is due to Serge Lang (Real and Functional Analysis) [5]. The theorem allows us to make statements about a function's value almost everywhere, depending on the value its integral takes on various sets of the measure space.

Before we introduce and prove the averaging theorem, we will first show the following lemma which is crucial for our proof. While not stated exactly in this manner, our proof makes use of the characterization of second-countable topological spaces given in the book General Topology by Ryszard Engelking (Theorem 4.1.15) [4]. (Engelking's book *General Topology*)

context *sigma_finite_measure*
begin

To show statements concerning σ-finite measure spaces, one usually shows the statement for finite measure spaces and uses a limiting argument to show it for the σ-finite case. The following induction scheme formalizes this.

lemma *sigma_finite_measure_induct*[*case_names finite_measure*, *consumes 0*]:
assumes $\bigwedge(N :: 'a\ measure)\ \Omega.\ finite_measure\ N \Longrightarrow N = restrict_space\ M\ \Omega \Longrightarrow \Omega \in sets\ M \Longrightarrow emeasure\ N\ \Omega \neq \infty \Longrightarrow emeasure\ N\ \Omega \neq 0 \Longrightarrow almost_everywhere\ N\ Q$
and [*measurable*]: *Measurable.pred M Q*
shows *almost_everywhere M Q*

An existence theorem for "improper" integrals. Hake's theorem implies that if the integrals over subintervals have a limit, the integral exists. We only need to assume that the integrals are bounded, and we get absolute integrability, but we also need a (rather weak) bound assumption on the function.

theorem *absolutely_integrable_improper*:
fixes $f :: 'M::euclidean_space \Rightarrow 'N::euclidean_space$
assumes *int_f*: ⋀*c d*. *cbox c d* ⊆ *box a b* ⟹ *f integrable_on cbox c d*

10.20.1 Local Lipschitz continuity

Given a function defined on a real interval, it is Lipschitz-continuous if and only if it is locally so, as proved in the following lemmas. It is useful especially for piecewise-defined functions: if each piece is Lipschitz, then so is the whole function. The same goes for functions defined on geodesic spaces, or more generally on geodesic subsets in a metric space (for instance convex subsets in a real vector space), and this follows readily from the real case, but we will not prove it explicitly.

We give several variations around this statement. This is essentially a connectedness argument.

We deduce that if a function is Lipschitz on finitely many closed sets on the real line, then it is Lipschitz on any interval contained in their union. The difficulty in the proof is to show that any point z in this interval (except the maximum) has a point arbitrarily close to it on its right which is contained in a common initial closed set. Otherwise, we show that there is a small interval $(z,\ T)$ which does not intersect any of the initial closed sets, a contradiction.

10.22.5 Fundamental theorem of calculus

Strong form of the fundamental theorem of calculus (Bartle's theorem). The derivative f' need only exist outside a negligible set S, provided the Henstock–Sacks condition holds: for every $0 < \varepsilon$ there is a gauge witnessing that the oscillation of f over any fine tagged partial division with all tags in S is small.

theorem *fundamental_theorem_of_calculus_Bartle*:
fixes *f* :: ‹*real* ⇒ *'a*::*real_normed_vector*› **and** *f'* :: ‹*real* ⇒ *'a*›
assumes *neg*: ‹*negligible S*›
and ‹*a* ≤ *b*›
and *deriv*: ‹⋀*x*. *x* ∈ {*a*..*b*} − *S* ⟹ (*f has_vector_derivative f' x*) (*at x within* {*a*..*b*})›

```

theory *Gamma_Function*
  imports
  Absolute_Continuity
  Summation_Tests
  Harmonic_Numbers
  HOL−Library.Nonpos_Ints
  HOL−Library.Periodic_Fun
begin

Several equivalent definitions of the Gamma function and its most important properties. Also contains the definition and some properties of the log-Gamma function and the Digamma function and the other Polygamma functions.

Based on the Gamma function, we also prove the Weierstraß product form of the sin function and, based on this, the solution of the Basel problem (the sum over all *1 / real* (n^2).

10.29.1 The Euler form and the logarithmic Gamma function

We define the Gamma function by first defining its multiplicative inverse *rGamma*. This is more convenient because *rGamma* is entire, which makes proofs of its properties more convenient because one does not have to watch out for discontinuities. (e.g. *rGamma* fulfils *rGamma z = z * rGamma (z + 1)* everywhere, whereas the Γ function does not fulfil the analogous equation on the non-positive integers)

We define the Γ function (resp. its reciprocale) in the Euler form. This form has the advantage that it is a relatively simple limit that converges everywhere. The limit at the poles is 0 (due to division by 0). The functional equation *Gamma (z + 1) = z * Gamma z* follows immediately from the definition.

definition *Gamma_series* :: ('*a* :: {*banach*,*real_normed_field*}) ⇒ *nat* ⇒ '*a* **where**

We now show that the series that defines the Γ function in the Euler form converges and that the function defined by it is continuous on the complex halfspace with positive real part.

We do this by showing that the logarithm of the Euler series is continuous and converges locally uniformly, which means that the log-Gamma function defined by its limit is also continuous.

This will later allow us to lift holomorphicity and continuity from the log-Gamma function to the inverse of the Gamma function, and from that to the Gamma function itself.

definition *ln_Gamma_series* :: ('*a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *nat* ⇒ '*a* **where**
ln_Gamma_series z n = *z* ∗ *ln* (*of_nat n*) − *ln z* − (∑ *k*=*1*..*n*. *ln* (*z* / *of_nat k* + *1*))

definition *ln_Gamma_series'* :: ('*a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ *nat* ⇒ '*a* **where**
ln_Gamma_series' z n =
− *euler_mascheroni*∗*z* − *ln z* + (∑ *k*=*1*..*n*. *z* / *of_nat n* − *ln* (*z* / *of_nat k* + *1*))

definition *ln_Gamma* :: ('*a* :: {*banach*,*real_normed_field*,*ln*}) ⇒ '*a* **where**
ln_Gamma z = *lim* (*ln_Gamma_series z*)

We now show that the log-Gamma series converges locally uniformly for all complex numbers except the non-positive integers. We do this by proving that the series is locally Cauchy.

We define a type class that captures all the fundamental properties of the inverse of the Gamma function and defines the Gamma function upon that.

This allows us to instantiate the type class both for the reals and for the complex numbers with a minimal amount of proof duplication.

class *Gamma* = *real_normed_field* + *complete_space* +
  fixes *rGamma* :: *'a* ⇒ *'a*
  assumes *rGamma_eq_zero_iff_aux*: *rGamma z* = *0* ⟷ (∃ *n*. *z* = − *of_nat n*)

10.29.7 The uniqueness of the real Gamma function

The following is a proof of the Bohr–Mollerup theorem, which states that any log-convex function G on the positive reals that fulfils $G(1) = 1$ and satisfies the functional equation $G(x + 1) = x\ G(x)$ must be equal to the Gamma function. In principle, if G is a holomorphic complex function, one could then extend this from the positive reals to the entire complex plane (minus the non-positive integers, where the Gamma function is not defined).
