1 Domain package examples theory Domain_ex imports HOLCF begin			
	_		
Do	omair	constructors are strict by default.	
do	main	d1 = d1a d1b "d1" "d1"	
leı	nma	"d1b $\cdot \perp \cdot y = \perp$ " by simp	
Co	nstrı	actors can be made lazy using the lazy keyword.	
do	main	d2 = d2a / d2b (lazy "d2")	
leı	nma	$"d2b \cdot x \neq \bot"$ by $simp$	
Strict and lazy arguments may be mixed arbitrarily.			

```
domain d3 = d3a / d3b (lazy "d2") "d2"
```

```
lemma "P (d3b \cdot x \cdot y = \bot) \longleftrightarrow P (y = \bot)" by simp
```

Selectors can be used with strict or lazy constructor arguments.

```
domain d4 = d4a | d4b (lazy d4b_left :: "d2") (d4b_right :: "d2")
```

```
lemma "y \neq \perp \implies d4b_{\text{left}} \cdot (d4b \cdot x \cdot y) = x" by simp
```

Mixfix declarations can be given for data constructors.

```
domain d5 = d5a | d5b (lazy "d5") "d5" (infixl <:#:> 70)
```

```
lemma "d5a \neq x :#: y :#: z" by simp
```

Mixfix declarations can also be given for type constructors.

```
domain ('a, 'b) lazypair (infixl <:*:> 25) =
  lpair (lazy lfst :: 'a) (lazy lsnd :: 'b) (infixl <:*:> 75)
```

```
lemma "\forall p::('a :*: 'b). p \sqsubseteq lfst \cdot p :*: lsnd \cdot p" by (rule allI, case_tac p, simp_all)
```

Non-recursive constructor arguments can have arbitrary types.

```
domain ('a, 'b) d6 = d6 "int lift" "'a \oplus 'b u" (lazy "('a :*: 'b) \times ('b \rightarrow 'a)")
```

Indirect recusion is allowed for sums, products, lifting, and the continuous function space. However, the domain package does not generate an induction rule in terms of the constructors.

```
domain 'a d7 = d7a "'a d7 \oplus int lift" | d7b "'a \otimes 'a d7" | d7c (lazy "'a d7 \rightarrow 'a")
```

— Indirect recursion detected, skipping proofs of (co)induction rules

Note that d7.induct is absent.

Indirect recursion is also allowed using previously-defined datatypes.

```
domain 'a slist = SNil | SCons 'a "'a slist"
```

```
domain 'a stree = STip | SBranch "'a stree slist"
```

Mutually-recursive datatypes can be defined using the and keyword.

```
domain d8 = d8a | d8b "d9" and d9 = d9a | d9b (lazy "d8")
```

Non-regular recursion is not allowed.

Mutually-recursive datatypes must have all the same type arguments, not necessarily in the same order.

```
domain ('a, 'b) list1 = Nil1 | Cons1 'a "('b, 'a) list2"
```

```
and ('b, 'a) list2 = Nil2 | Cons2 'b "('a, 'b) list1"
Induction rules for flat datatypes have no admissibility side-condition.
domain 'a flattree = Tip | Branch "'a flattree" "'a flattree"
\mathbf{lemma} \ "\llbracket P \perp ; \ P \ Tip; \ \bigwedge x \ y. \ \llbracket x \neq \bot; \ y \neq \bot; \ P \ x; \ P \ y \rrbracket \implies P \ (\mathit{Branch} \cdot x \cdot y) \rrbracket
\implies P x''
by (rule flattree.induct) — no admissibility requirement
Trivial datatypes will produce a warning message.
domain triv = Triv triv triv
  — domain Domain_ex.triv is empty!
lemma "(x::triv) = \perp" by (induct x, simp_all)
Lazy constructor arguments may have unpointed types.
domain natlist = nnil | ncons (lazy "nat discr") natlist
Class constraints may be given for type parameters on the LHS.
domain ('a::predomain) box = Box (lazy 'a)
domain ('a::countable) stream = snil | scons (lazy "'a discr") "'a stream"
      Generated constants and theorems
domain 'a tree = Leaf (lazy 'a) | Node (left :: "'a tree") (right ::
"'a tree")

1.2 Known bugs

Declaring a mixfix with spaces causes some strange parse errors.

end

2 Fixrec package examples

```
theory Fixrec_ex imports HOLCF begin
```

2.1 Basic fixrec examples

Fixrec patterns can mention any constructor defined by the domain package, as well as any of the following built-in constructors: Pair, spair, sinl, sinr, up, ONE, TT, FF.

Typical usage is with lazy constructors.

```
fixrec down :: "'a u \rightarrow 'a" where "down \cdot (up \cdot x) = x"
```

With strict constructors, rewrite rules may require side conditions.

```
fixrec from_sinl :: "'a \oplus 'b \rightarrow 'a" where "x \neq \bot \Longrightarrow from_sinl·(sinl·x) = x"
```

Lifting can turn a strict constructor into a lazy one.

```
fixrec from_sinl_up :: "'a u \oplus 'b \rightarrow 'a" where "from_sinl_up \cdot (sinl \cdot (up \cdotx)) = x"
```

Fixrec also works with the HOL pair constructor.

```
fixrec down2 :: "'a u \times 'b u \rightarrow 'a \times 'b" where "down2 (up \cdotx, up \cdoty) = (x, y)"
```

2.2 Examples using fixrec_simp

A type of lazy lists.

```
domain 'a llist = lNil | lCons (lazy 'a) (lazy "'a llist")
```

A zip function for lazy lists.

Notice that the patterns are not exhaustive.

fixrec

```
lzip :: "'a llist \rightarrow 'b llist \rightarrow ('a \times 'b) llist" where "lzip·(lCons·x·xs)·(lCons·y·ys) = lCons·(x, y)·(lzip·xs·ys)" | "lzip·lNil·lNil = lNil"
```

fixrec_simp is useful for producing strictness theorems.

Note that pattern matching is done in left-to-right order.

```
lemma 1zip\_stricts [simp]:

"1zip \cdot \bot \cdot ys = \bot"

"1zip \cdot 1Ni1 \cdot \bot = \bot"

"1zip \cdot (1Cons \cdot x \cdot xs) \cdot \bot = \bot"

by fixrec\_simp +

fixrec\_simp can also produce rules for missing cases.

lemma 1zip\_undefs [simp]:

"1zip \cdot 1Ni1 \cdot (1Cons \cdot y \cdot ys) = \bot"

"1zip \cdot (1Cons \cdot x \cdot xs) \cdot 1Ni1 = \bot"
```

2.3 Pattern matching with bottoms

by fixrec_simp+

As an alternative to using <code>fixrec_simp</code>, it is also possible to use bottom as a constructor pattern. When using a bottom pattern, the right-hand-side must also be bottom; otherwise, <code>fixrec</code> will not be able to prove the equation.

```
fixrec from_sinr_up :: "'a \oplus 'b_{\perp} \rightarrow 'b" where "from_sinr_up\cdot \bot = \bot"
```

 $| "from_sinr_up \cdot (sinr \cdot (up \cdot x)) = x"$

If the function is already strict in that argument, then the bottom pattern does not change the meaning of the function. For example, in the definition of <code>from_sinr_up</code>, the first equation is actually redundant, and could have been proven separately by <code>fixrec_simp</code>.

A bottom pattern can also be used to make a function strict in a certain argument, similar to a bang-pattern in Haskell.

```
fixrec

seq :: "'a \rightarrow 'b \rightarrow 'b"

where

"seq·\bot·y = \bot"

| "x \neq \bot \Longrightarrow seq·x·y = y"
```

2.4 Skipping proofs of rewrite rules

Another zip function for lazy lists.

Notice that this version has overlapping patterns. The second equation cannot be proved as a theorem because it only applies when the first pattern fails.

fixrec

```
lzip2 :: "'a llist \rightarrow 'b llist \rightarrow ('a \times 'b) llist" where "lzip2 \cdot (lCons \cdot x \cdot xs) \cdot (lCons \cdot y \cdot ys) = lCons \cdot (x, y) \cdot (lzip2 \cdot xs \cdot ys)" (unchecked) "lzip2 \cdot xs \cdot ys = lNil"
```

Usually fixrec tries to prove all equations as theorems. The "unchecked" option overrides this behavior, so fixrec does not attempt to prove that particular equation.

Simp rules can be generated later using fixrec_simp.

```
lemma 1zip2\_simps [simp]:

"1zip2 \cdot (1Cons \cdot x \cdot xs) \cdot 1Ni1 = 1Ni1"

"1zip2 \cdot 1Ni1 \cdot (1Cons \cdot y \cdot ys) = 1Ni1"

"1zip2 \cdot 1Ni1 \cdot 1Ni1 = 1Ni1"

by fixrec\_simp+

lemma 1zip2\_stricts [simp]:

"1zip2 \cdot \bot \cdot ys = \bot"

"1zip2 \cdot (1Cons \cdot x \cdot xs) \cdot \bot = \bot"

by fixrec\_simp+
```

2.5 Mutual recursion with fixrec

Tree and forest types.

```
domain 'a tree = Leaf (lazy 'a) | Branch (lazy "'a forest")
and 'a forest = Empty | Trees (lazy "'a tree") "'a forest"
```

To define mutually recursive functions, give multiple type signatures separated by the keyword and.

fixrec

```
 \begin{array}{l} \operatorname{map\_tree} \ :: \ "(\ 'a \ \to \ 'b) \ \to \ (\ 'a \ \operatorname{tree} \ \to \ 'b \ \operatorname{tree})" \\ \operatorname{and} \\ \operatorname{map\_forest} \ :: \ "(\ 'a \ \to \ 'b) \ \to \ (\ 'a \ \operatorname{forest} \ \to \ 'b \ \operatorname{forest})" \\ \operatorname{where} \\ \operatorname{"map\_tree} \cdot f \cdot (\operatorname{Leaf} \cdot x) \ = \ \operatorname{Leaf} \cdot (f \cdot x)" \\ \operatorname{"map\_tree} \cdot f \cdot (\operatorname{Branch} \cdot ts) \ = \ \operatorname{Branch} \cdot (\operatorname{map\_forest} \cdot f \cdot ts)" \\ \operatorname{"map\_forest} \cdot f \cdot \operatorname{Empty} \ = \ \operatorname{Empty}" \\ \operatorname{"ts} \ \neq \ \bot \ \Longrightarrow \\ \operatorname{map\_forest} \cdot f \cdot (\operatorname{Trees} \cdot t \cdot ts) \ = \ \operatorname{Trees} \cdot (\operatorname{map\_tree} \cdot f \cdot t) \cdot (\operatorname{map\_forest} \cdot f \cdot ts)" \\ \operatorname{lemma} \ \operatorname{map\_tree\_strict} \ [\operatorname{simp}] : \ "\operatorname{map\_tree} \cdot f \cdot \bot \ = \ \bot" \\ \operatorname{by} \ fixrec\_simp} \\ \end{array}
```

```
lemma map_forest_strict [simp]: "map_forest\cdot f \cdot \bot = \bot" by fixrec_simp
```

2.6 Looping simp rules

The defining equations of a fixrec definition are declared as simp rules by default. In some cases, especially for constants with no arguments or functions with variable patterns, the defining equations may cause the simplifier to loop. In these cases it will be necessary to use a [simp del] declaration.

fixrec

```
repeat :: "'a \rightarrow 'a llist"
where
[simp del]: "repeat·x = 1Cons \cdot x \cdot (repeat \cdot x)"
```

We can derive other non-looping simp rules for repeat by using the subst method with the repeat.simps rule.

```
lemma repeat_simps [simp]:

"repeat x \neq \bot"

"repeat x \neq \bot"

"repeat x \neq \bot Nil"

"repeat x \neq \bot Simps x \neq \bot Point x \neq
```

For mutually-recursive constants, looping might only occur if all equations are in the simpset at the same time. In such cases it may only be necessary to declare [simp del] on one equation.

fixrec

```
inf_tree :: "'a tree" and inf_forest :: "'a forest"
where
  [simp del]: "inf_tree = Branch·inf_forest"
| "inf_forest = Trees·inf_tree·(Trees·inf_tree·Empty)"
```

2.7 Using fixrec inside locales

```
locale test =  fixes foo :: "'a \rightarrow 'a"  assumes foo\_strict: "foo \cdot \bot = \bot " begin fixrec bar :: "'a u \rightarrow 'a" where "bar \cdot (up \cdot x) = foo \cdot x" lemma bar \ strict: "bar \cdot \bot = \bot "
```

```
by fixrec_simp
end
```

3 Definitional domain package

```
theory New_Domain
imports HOLCF
begin
```

UPDATE: The definitional back-end is now the default mode of the domain package. This file should be merged with <code>Domain_ex.thy</code>.

Provided that domain is the default sort, the new_domain package should work with any type definition supported by the old domain package.

```
domain 'a llist = LNil | LCons (lazy 'a) (lazy "'a llist")
```

The difference is that the new domain package is completely definitional, and does not generate any axioms. The following type and constant definitions are not produced by the old domain package.

```
thm type_definition_llist
thm llist_abs_def llist_rep_def
```

The new domain package also adds support for indirect recursion with userdefined datatypes. This definition of a tree datatype uses indirect recursion through the lazy list type constructor.

```
domain 'a ltree = Leaf (lazy 'a) | Branch (lazy "'a ltree llist")
```

For indirect-recursive definitions, the domain package is not able to generate a high-level induction rule. (It produces a warning message instead.) The low-level reach lemma (now proved as a theorem, no longer generated as an axiom) can be used to derive other induction rules.

```
thm ltree.reach
```

The definition of the take function uses map functions associated with each type constructor involved in the definition. A map function for the lazy list type has been generated by the new domain package.

```
thm ltree.take_rews
thm llist_map_def

lemma ltree_induct:
  fixes P :: "'a ltree ⇒ bool"
  assumes adm: "adm P"
  assumes bot: "P ⊥"
```

```
assumes Leaf: "\bigwedge x. P (Leaf·x)"
  assumes Branch: "\bigwedge f 1. \forall x. P (f \cdot x) \implies P (Branch·(llist_map·f·l))"
  shows "P x"
proof -
  have "P (\bigsqcup i. ltree_take i·x)"
  using adm
  proof (rule admD)
    fix i
    show "P (ltree_take i \cdot x)"
    proof (induct i arbitrary: x)
       case (0 x)
       show "P (ltree_take 0 \cdot x)" by (simp add: bot)
    next
      case (Suc n x)
      show "P (ltree_take (Suc n)·x)"
         apply (cases x)
         apply (simp add: bot)
         apply (simp add: Leaf)
         apply (simp add: Branch Suc)
    qed
  qed (simp add: ltree.chain_take)
  thus ?thesis
    by (simp add: ltree.reach)
qed
\quad \text{end} \quad
```
